Existing classes of internal combustion engine piston assemblies are not able to meet the upcoming Tier 4 emissions standards in the United States. Even the Tier 4i emissions standard is not believed feasible, with practical combustion systems. A fuel reformer, however, can produce a hydrogen-rich reformed fuel that can meet the stringent emission requirements. Fuel reformers are well known in the art. Gasoline reformers are a type of fuel reformer. The object of the reformer is to convert the fuel to a hydrogen-rich fuel that can be burned in internal combustion engines. Known processes for converting gasoline to reformat involve heating the gasoline in the presence of a catalyst and water. The resulting reformed gas is sent to an engine. Hydrogen is produced during the process. The presence of carbon dioxide (CO₂) in the reformed gas reduces the H₂ produced. Carbon dioxide may be produced by several processes including the reaction of hydrocarbons and water at elevated temperatures and pressures in the presence of a catalyst. One existing gasoline reformer is a reactor that uses steam to generate a hydrogen-rich reformed gas. The reactor has a furnace that heats a gasoline-water mixture to a temperature greater than 700° C. A catalyst is provided at a high temperature. This catalyst will convert carbon monoxide (CO) and hydrocarbons in the fuel to carbon dioxide (CO₂) and hydrogen. One problem with this process is that carbon dioxide is produced, and in order to reduce the carbon dioxide to acceptable levels, the engine exhaust stream is sent to a CO₂ scrubber. The scrubber removes the carbon dioxide./*
