This bottom panel shows the actual adjustment on the_ _layer that was edited. The layers stack from bottom to top in the Layers palette, as shown here._ Photoshop has a host of other features that all users must learn, as well as a growing selection of plug-ins available from third-party providers that expand Photoshop's functionality. In this chapter, we will focus on the fundamentals of using Photoshop to manipulate color, but in a later chapter we will highlight more advanced functionality. ## The Layers Panel The Layers panel is arguably the most important component to Photoshop; you'll need to understand how to use it very efficiently to be able to extract the best results from your images. **Figure 5.14** The Layers panel is the most important tool in Photoshop for working with layers. At the top of the Layers panel (see figure 5.14) you'll see the layer name and thumbnail of the current layer that is currently being viewed. If you go to View→Layers, you can see all of the layers that you have open in the view window and access their thumbnails (shown in the bottom panel of figure 5.14). You use the Layer drop-down menu on the left side of the Layers panel to quickly switch between different layers. To change the active layer, simply click on the name of the layer you want to work on. An "x" appears to the right of the active layer's name, and the layer is not visible. To bring this layer into view, drag it from the Layer menu to bring it to the front of the stack (top layer). You can also use the keyboard shortcuts ALT-CTRL-SHIFT+B (PC: ALT-CTRL-SHIFT+N) to bring layers to the front. Once the active layer is front and center, you can use the controls on the top of the Layers panel to rearrange the order of the layers. The two key Layers buttons are the Close and Lock buttons, which are located directly above the layer thumbnail. Clicking on these buttons will close all open layers and lock the current layer in its current position so that it cannot be moved. Note that if you are working on a document that

The present study was carried out in order to determine if calmodulin (CaM) inhibits cAMP-dependent endogenous protein kinase from fast skeletal muscle. Incubation of homogenates of fast skeletal muscle with 500 microM Ca2+, 10 mM ATP, and 0.15 mM cAMP under conditions that allow activity of the endogenous protein kinase resulted in an approximately four-fold stimulation of [3H]phosvate incorporation into endogenous substrates. This increase was not inhibited by EGTA, NaF, nor was it altered by the addition of calmodulin. Incubation of homogenates with 500 microM Ca2+, 10 mM ATP, and 0.15 mM cAMP under conditions that permit activation of the endogenous protein kinase by Ca2+ alone resulted in a stimulation that was not altered by EGTA, NaF, nor was it altered by the addition of calmodulin. However, the net increase in [3H]phosvate incorporation was greater when calmodulin was added to the reactions, suggesting that endogenous CaM may be present in low concentrations in fast skeletal muscle. Incubation of muscle homogenates with 500 microM Ca2+, 10 mM ATP, and 0.15 mM cAMP under conditions that allow activation of the endogenous protein kinase by 5 mM Ca2+ or Ca2+ plus CaM resulted in an approximately four-fold stimulation of [3H]phosvate incorporation into endogenous substrates. This increase was not inhibited by EGTA, NaF, nor was it altered by the addition of calmodulin. However, the net increase in [3
