I like to say that I love Word and there is no doubt about that. There are things that are great about it. And there are also things that could be improved about it. All in all, if you like to make your documents more professional and save them in the correct way, then I suggest you to get yourself a copy. But the thing is not so much about the great things about Word, but more about the bad ones. And here is where most of us have problems with it. Can you remember the last time you sent a document to somebody and the result was not as expected? It could be that the way you saved it was not the one that was supposed to be used. And then you realized you were doing something wrong. It could be that 77a5ca646e

I'm going through some of the MSDN samples of how to develop with C#. I came across a couple of posts where the poster created and used a number of instances of a class and did not release those instances from memory. My question is, are the objects in memory only as long as the program is running? I'm asking this because if the application crashes, the objects are not being released. A: That's right. C# has the Garbage Collector. It will collect unreferenced objects at a suitable time (when memory gets tight) so it is more or less left to you to decide when to release objects. And the GC will perform this "work" when it knows it is a good time to do it - not when it thinks you are about to do something that will reduce the overall amount of memory available (for example, allocating more memory) Note that while objects do not need to be explicitly released, objects which are inside arrays of some type (List for example) need to be explicitly released to avoid memory leaks. This is because when an array is no longer needed, the array will still take up space in memory. This space will be allocated by the GC for the array's contents but the GC does not need to know that the array itself is no longer in use. That's why we can have arrays of Objects (i.e. not a List) and they can be collected by the GC. A: Yes, managed objects are collected by the GC when memory runs low. This is typically triggered automatically by a certain

There is life in the depths: Acidic water creates an ideal ecosystem for microbes. But we don’t know what they are. Do they eat the organic matter we send to the depths of the ocean? Or are they eating each other? On the other hand, we know that things go wrong with oxygen and methane, and animals and microbes also die. We don’t know how that happens, but we do know that it happens. We know that the ocean surface is controlled by some of the least understood processes in the Earth’s atmosphere, the cycling of carbon. The sea surface is kept in check by a slow carbon sink that traps the greenhouse gases carbon dioxide and methane. This sink is also the source of oxygen and nutrients that allow microorganisms and organisms at the base of the food chain to survive and multiply. We have an idea of what is going on, and of what is likely to happen with the ocean surface. But beneath that surface we see the colors and shapes of the living ocean. The young marine biologist who came up with the above question was stationed at the Woods Hole Oceanographic Institution. Woods Hole is a part of the world known as Cape Cod. It is a place of cold, dark, windswept weather, and dark forests. “I was literally in this building with a window. It was a small window, almost like a peephole. It was sort of like, ‘Look, there is this submarine.’” Huge, steep mountains soar above the ocean floor. They are called seamounts, and there are hundreds of thousands of them on the North Atlantic seafloor. For centuries, sailors have explored the oceans, and countless tales of adventures in the depths were recorded. The sea was thought to be the ultimate pit of eternal darkness. But in that darkness, and in the vast ocean, lie glimmerings of life. Life has moved to the depths. We’ve explored the deep ocean for generations. Recently, we’ve found more life in the deep ocean than we knew existed. Last year, we discovered a huge “pond” of jellyfish. Plumes of methane leak from the
