Atmospheric deposition fluxes of antimony as a function of ambient land use and exceedance of intake guidelines: effects of vegetation. In a previous study, it was shown that vegetation near a road affected airborne concentrations of Sb in roadside air, as did ambient land use. The relationship between the overall rate of Sb deposition and road traffic intensity was also demonstrated in that study. In this paper, the results are extended to examine the relationship of atmospheric deposition rates to ambient land use, climatic and meteorological conditions and to exceedance of intake guidelines. The results show that climatic and meteorological conditions have more influence on airborne Sb concentrations than does land use, which is consistent with observations in previous studies. Furthermore, a critical situation was found for roadside air: when the air masses contain high concentrations of Sb, dense vegetation is required for the removal of Sb, since air turbulence influences the free dispersion of Sb from the roadside. For ambient air, the deposition rate increases with ambient land use, with a maximum for forest land. Furthermore, the deposition rate increases in highland areas, although most likely to a lesser extent than for ambient air. In addition, Sb deposition from all three land uses studied (commercial, industrial and rural) is greater than for highway roadside air. The deposition of Sb from the three land uses was generally not found to be affected by temperature, with the exception of roadside air at lower wind speeds (less than 10 m/s). For roadside air, the deposition was generally higher in summer than in winter and higher in winter than in autumn. The deposition of Sb from ambient air was found to decrease with wind speed, and this decrease was not found for roadside air. The deposition of Sb from ambient air was greater than for the other land uses. The background description provided herein is for the purpose of generally presenting the context of the disclosure. Wireless local area networks (WLANs) are deployments of wireless networks that operate in a licensed (i.e., regulated) frequency spectrum. Typically, communication protocols are established so that wireless access points (APs) operate in a coordinated manner within the licensed spectrum. Because different APs are often located in different geographical locations

Q: What is the relation between brown rice and white rice? I read that brown rice is preferred over white rice because it contains nutrients, like folic acid and fiber, which are lost when rice goes to white rice. Is this accurate? A: In general, rice is a good source of carbohydrates but, when consumed in large amounts over an extended period of time, a white rice diet may promote a higher risk of diabetes (Aguirre JV, et al. 2012). Brown rice, however, is part of a healthy diet. White rice is a rice variety that is extremely refined and that is usually made from uncooked grains (Eur J Nutr 2009). In contrast, brown rice is a whole grain variety that has not been exposed to any refinements and is usually made from uncooked grains. Furthermore, brown rice is a special food because it contains more nutrients than white rice. Brown rice provides much more bran, but also iron, potassium, and fiber (J Am Diet Assoc 2008). Whole grains (eating the entire grain) are nutrient-dense and may be preferable to refined grains (eating only the endosperm, starch, or the endosperm, starch, and bran) because whole grains are a more balanced source of carbohydrates, fiber, and phytochemicals (Pemberton 2008). Whole grains are nutrients-dense foods with all three parts of the grain contributing to the complete nutrient profile of the food. They are highly nutritious and are associated with a lower risk of non-communicable diseases, including cardiovascular diseases, type 2 diabetes, certain cancers, and obesity (Moscicki 2005). However, like other types of carbohydrates, white rice also stimulates the metabolism by activating the pancreas to release insulin, so people with diabetes should limit their intake to under 50-60 grams (less than 2 servings) per day (Scherer et al. 2004). However, research shows that intake of 100 grams or more (3-4 servings) of white rice a day has little effect on blood sugar or insulin sensitivity (Hurst et al. 2011). Brown rice is a whole grain, with the bran coating surrounding the endosperm. The outer portion of the grain contains a significant amount of fiber. Whole grains contain fiber in their intact form that is composed of intact cell wall-bound and soluble dietary fibers. However, dietary fiber is also commonly referred to as ♦
