This is the open-source version of our paid version from Memory usage and memory leaks

Memory usage is a very important aspect of a computer system. It is the space taken up by the system and its various components. As applications run, they consume memory. The more applications that are running, the more memory is required. Some programs use a lot more memory than others. While some software applications are multi-threaded, they only require a certain amount of memory. At some point, the software application will need more memory than is available and this situation will lead to an Out Of Memory situation.

Memory leaks

Memory leaks are situations where a software application is using memory, but is not releasing it back to the system. In this example, the software application is using memory, but it is not giving it back. Memory leaks are very common in programs and can cause a software application to run out of memory.

Memory usage indication

Memory usage indications are normally included in the Task Manager as a graph. The program using the most memory will take up the majority of the space in the graph. If there is more than one type of memory taking up memory, it will appear as many parallel lines in the graph. This way, it is possible to see which application is taking up the most memory. Common memory usage indicators include:

- System
- Pagefile
- Private
- Available
- Committed
- Working set
- Memory Leaks
- Hidden processes
