Malware bypasses traditional methods of detection Bypassing traditional anti-malware detection methods isn't new in the world of cyber-crime, but it has become increasingly common in recent years. Malware which once relied on the legacy signature-based detection methods has grown to develop its own methods of evading detection and spreading through vulnerable endpoints. The particular ways this evasion happens could be dependent on the malware, but some common tactics involve: NOP sleds This is a simple way to disguise malicious code as legitimate, which in turn makes it more difficult for anti-malware software to detect. The malware would modify the code, which in turn creates a new file. The new file contains NOPs (no operation instructions), which essentially instructs the CPU to ignore the instructions in the code. By modifying the valid code, the malware is able to evade detection. Analysis of binary samples demonstrates the usage of NOP sleds, for example, binary translation or Unicode homoglyph attacks (e.g. a modified character is used in the same way as a valid one, and this would mask the fact that the text is modified). To evade detection through
